A Definitive Study of Cosmic Dust in the Local Universe

Manolis Xilouris

National Observatory of Athens

# DustPedia

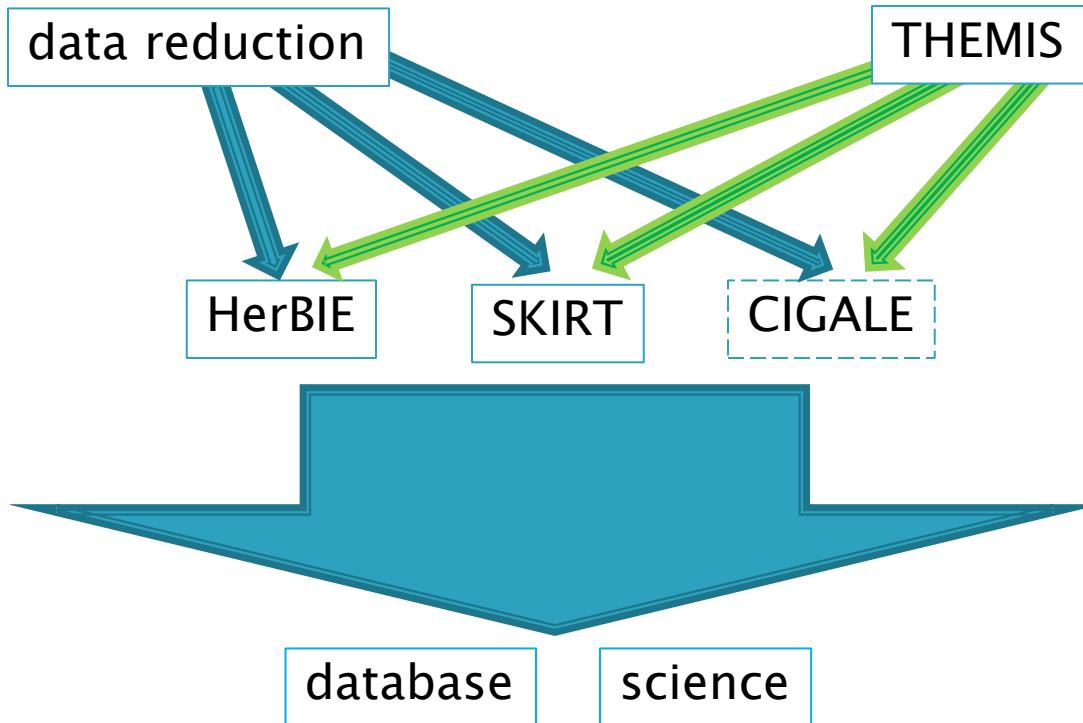

DustPedia is a project funded by the EU (grant agreement number 606847) under the heading 'Exploitation of space science and exploration data (FP7-SPACE-2013-1)' and is a collaboration of six European institutes: Cardiff University (UK), National Observatory of Athens (Greece), Instituto Nazionale di Astrofisica (Italy), Universiteit Gent (Belgium), Commissariat à l'énergie atomique (France), Université Paris Sud (France).

## Objectives

- Create a multiwavelength imagery and photometry database of all nearby galaxies with Herschel observations.
- Analyze the data using state-of-the-art dust grain model included in Radiative Transfer and SED fitting tools.
- Derive scaling relations of fundamental parameters for galaxies of different morphological types and environment.
- Update the database with the model derived parameters.

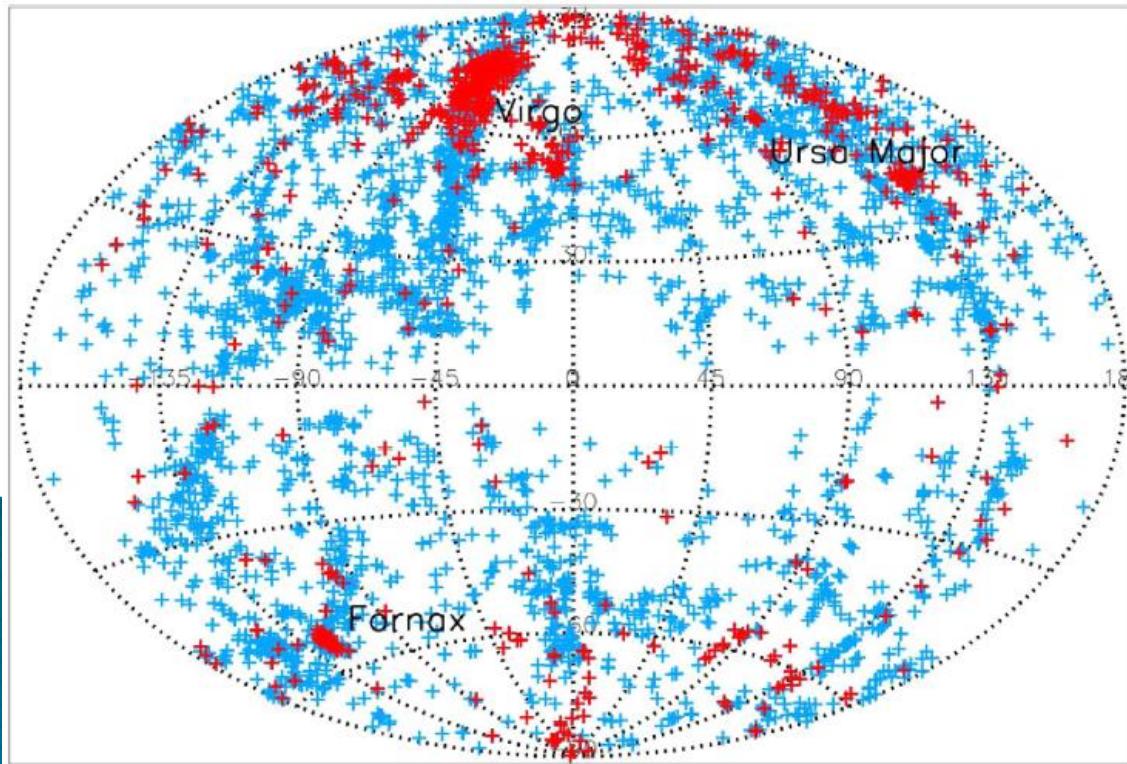

# The DustPedia strategy

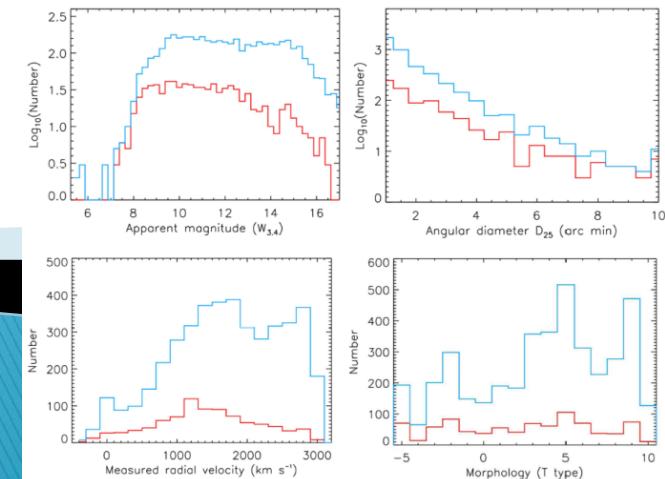

# The DustPedia sample

4259 galaxies within  $D=40$  Mpc, detected at WISE 3.4  $\mu\text{m}$  and with size greater than 1 arcminute.

875 galaxies with Herschel detections.

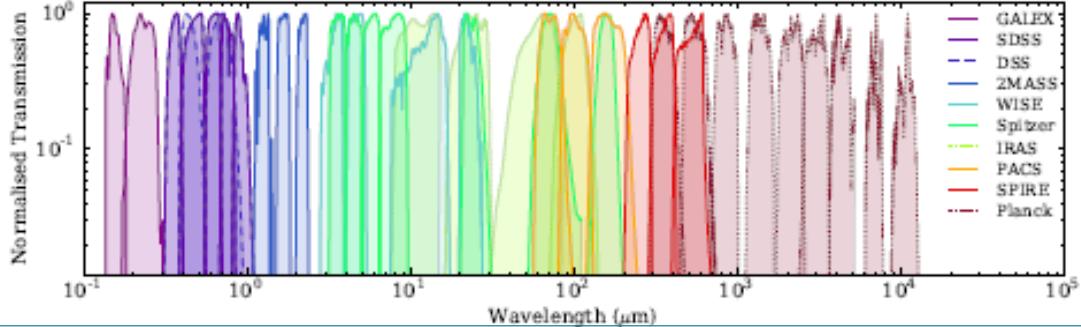

Selection Criterion	Number
LEDA	4259
LEDA+WISE <sub>5<math>\sigma</math></sub>	4231
LEDA+WISE <sub>5<math>\sigma</math></sub> +PACS	829
LEDA+WISE <sub>5<math>\sigma</math></sub> +SPIRE	907
LEDA+WISE <sub>5<math>\sigma</math></sub> +PACS+SPIRE	798
LEDA+WISE <sub>5<math>\sigma</math></sub> +PACS/SPIRE+Inspection	876

THEMIS

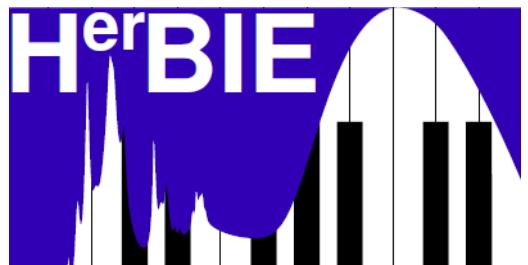

# The Heterogeneous dust Evolution Model for Interstellar Solids

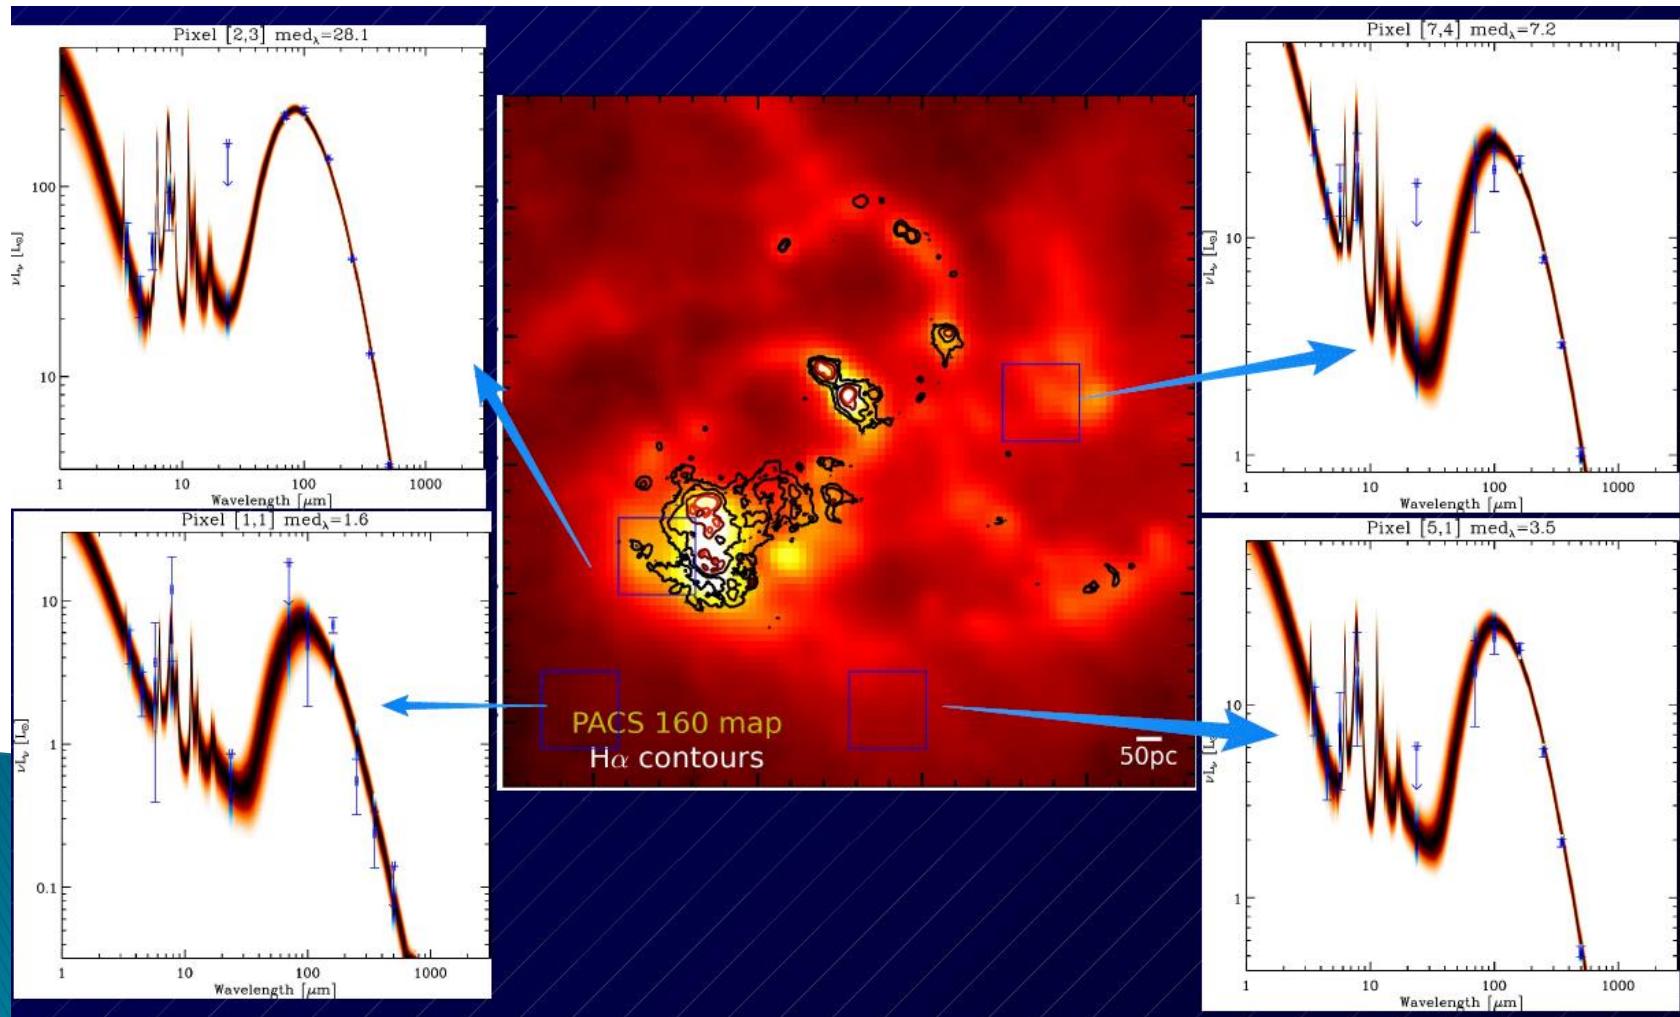

<http://www.ias.u-psud.fr/themis/>

THEMIS is a self-consistent, unifying and global dust modelling framework, which is built upon the properties of amorphous hydrocarbon and amorphous silicate materials that have been measured in the laboratory (Jones et al. 2013, 2014). The main difference between THEMIS and previous grain models is in how small carbon grains are treated. Previous dust mixtures assumed neutral and charged PAHs to reproduce aromatic features, and small graphite or amorphous carbons to account for the mid-IR continuum. The THEMIS dust model accounts for this ensemble of observables with hydrogenated amorphous carbons (HACs). THEMIS has been developed to include the evolution of these materials and the dust size distribution in the transition to dense regions (Ysard et al. 2015a and b, Jones et al. 2017), and in energetic regions (Bocchio et al. 2012, 2013, 2014), to explain H<sub>2</sub> formation in PDRs (Jones & Habart 2015) and provide a link with elemental depletions and the diffuse interstellar bands (Jones 2013, 2014). Full details of the THEMIS model are described in Jones et al. (2017).

# Morphology of the galaxies

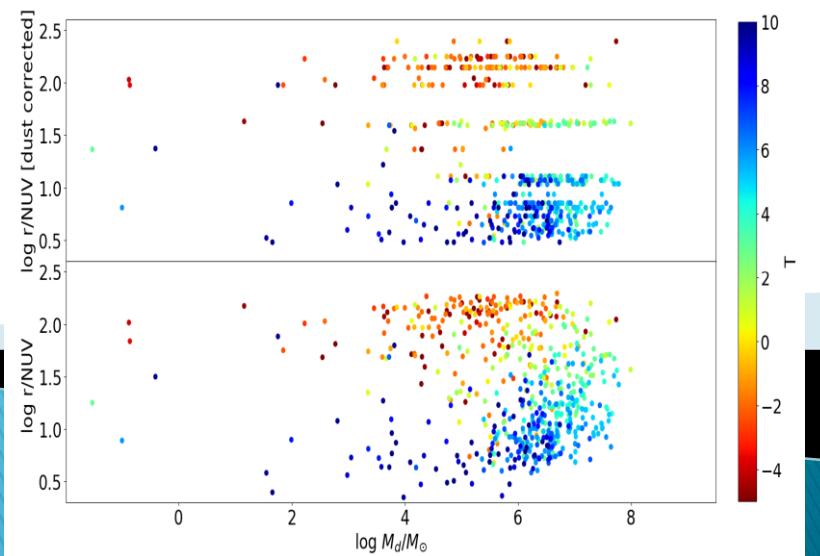

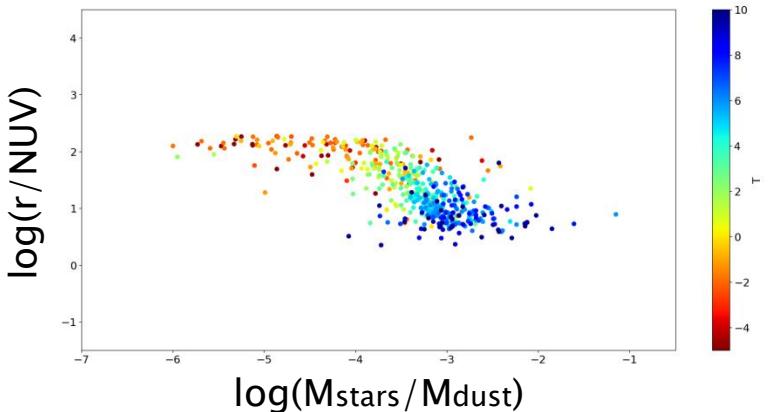

"Radial distribution of dust, stars, gas, and star-formation rate in DustPedia face-on galaxies"  
 Casasola et al. 2017, A&A, in press

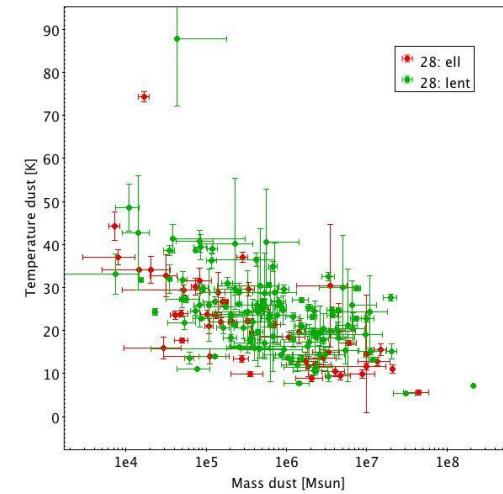

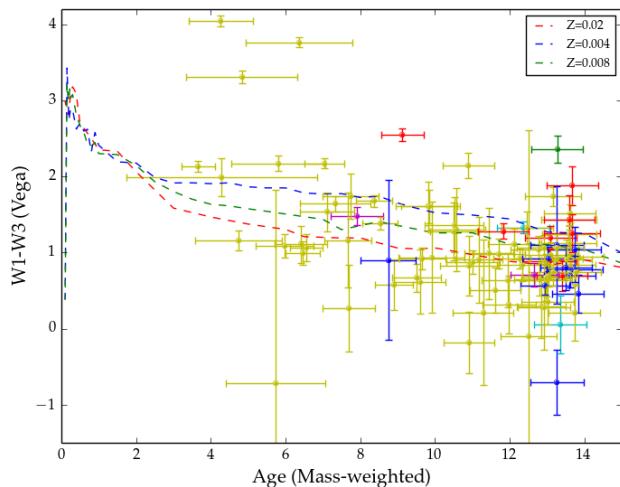

# Scaling relations

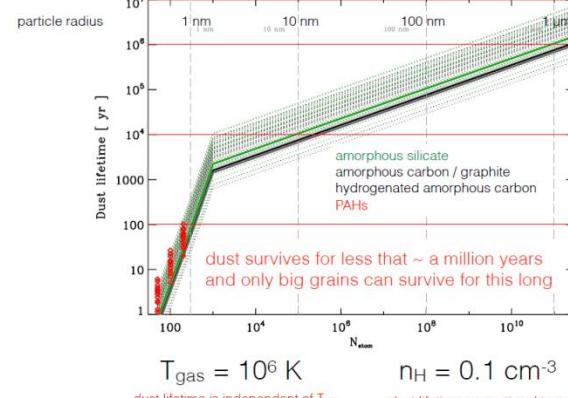

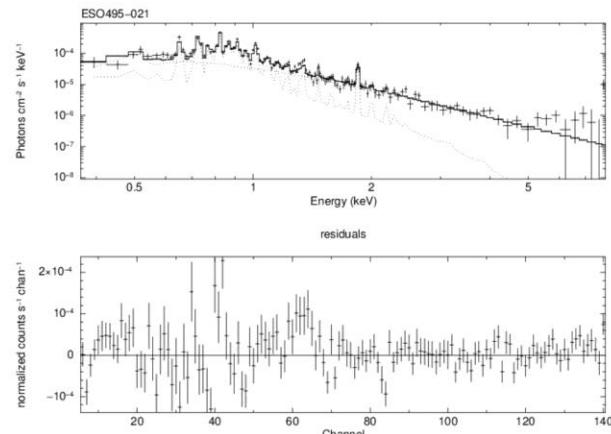

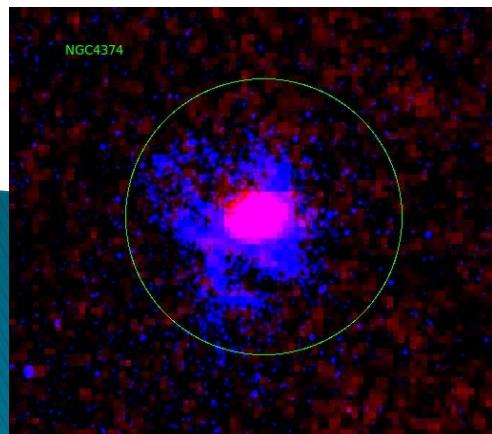

Distribution of the DustPedia galaxies in the  $M_{\text{dust}}$ ,  $M_{\text{stars}}$ ,  $SFR$  volume.

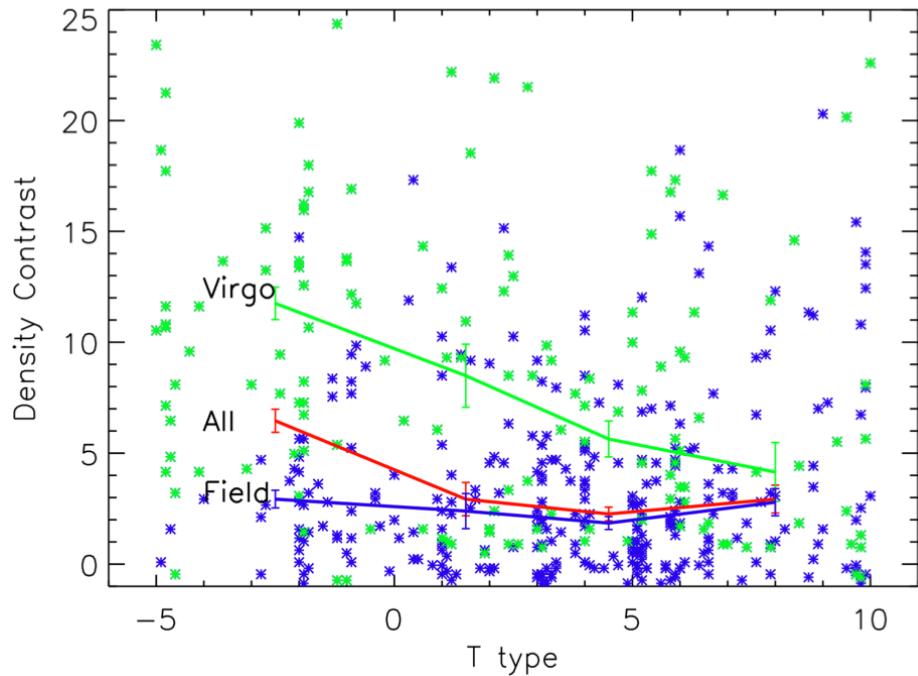

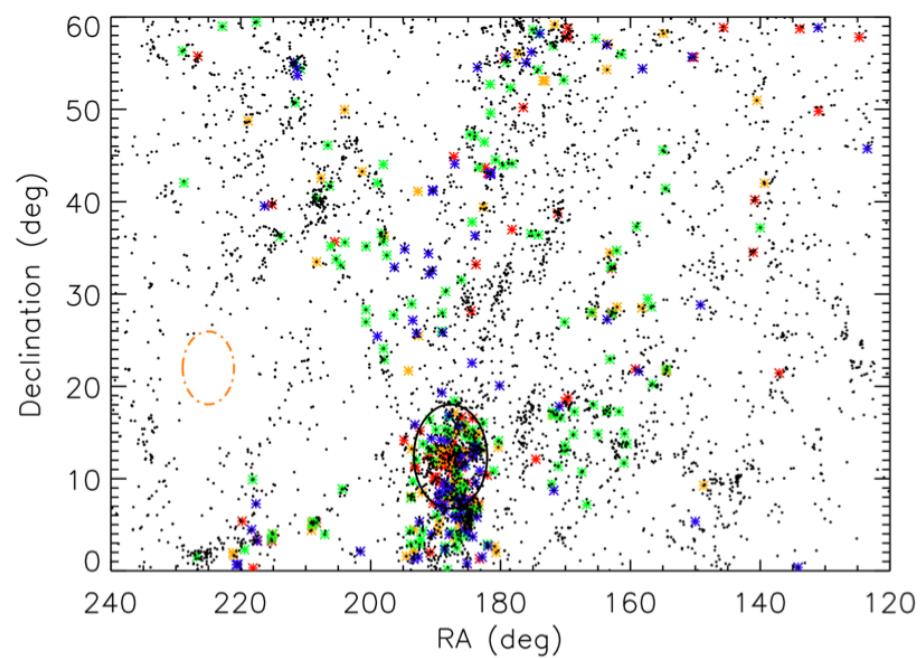

# Early-type galaxies

Investigate the dust lifetimes and relative contributions of photon versus electron collisional heating of dust grains and the survival of the dust grains of different sizes in these galaxies.

# Environmental effects on DustPedia galaxies

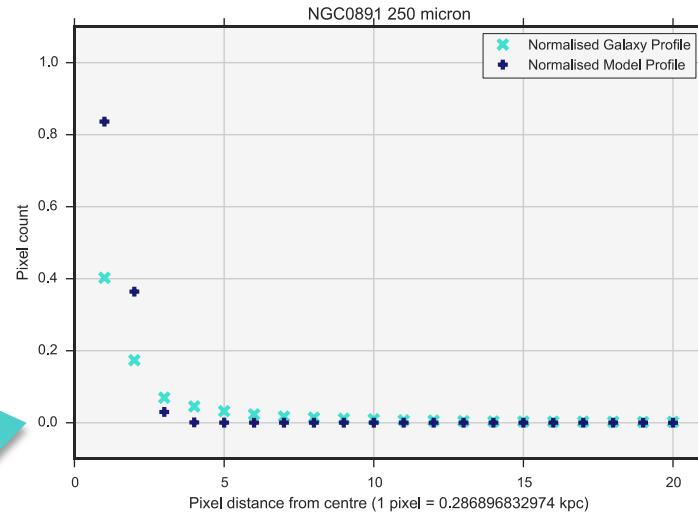

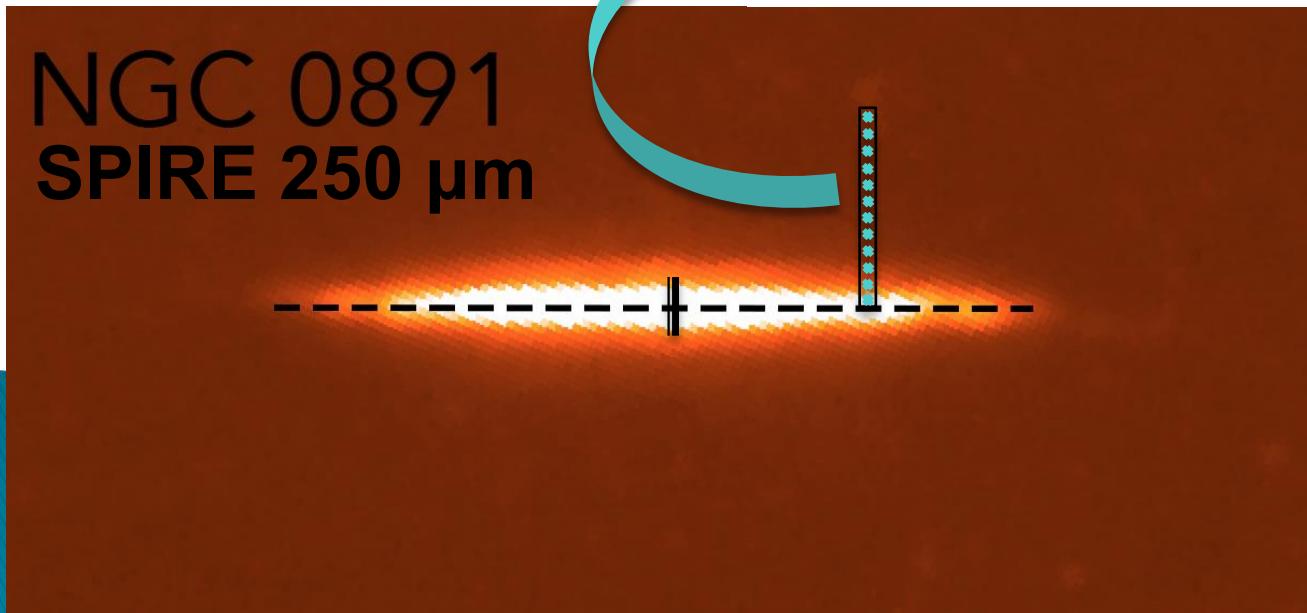

We are carrying out an investigation into how the local environment may affect the properties of DustPedia galaxies.

We have dust mass and temperature, stellar mass and star formation rates (WISE 12 $\mu$ ) and a density contrast parameter (using SDSS galaxies).

## DustPedia

A Definitive Study of Cosmic Dust in the Local Universe

[Learn more >](#)

### Overview

DustPedia is a project funded by the EU under the heading "Exploitation of space science and exploration data". It is a collaboration of six European institutes with a primary goal of exploiting existing data in the *Herschel* Space Observatory and *Planck* Telescope databases. This data will be combined with other available data from both ground based and space based telescopes to make the most extensive and intensive study of galaxies in the nearby Universe.

### Objectives

**SED Fitting**  
Measure the complete UV/mm/radio spectral energy distribution (SEDs) for a large number ( $> 1000$ ) of galaxies, and for different environments within individual galaxies.

**Dust Evolution**  
Determine how the dust NIR-mm/radio SED evolves throughout the Universe and how this is related to the underlying dust properties?

**Cosmological Implications**  
Derive dust mass functions to the lowest-possible luminosities and masses and to compare these with cosmological surveys and the cosmic infrared background.

**Radiative Transfer Modelling**  
Interpret the galaxy SEDs using radiative transfer and full SED models, to derive stellar, gas and dust properties, star formation rates and histories as a function of morphological type.

**A Global Dust Model**  
Develop a dust evolution model that is consistent with the SEDs of galaxies of different morphological types and determine the primary sources and sinks for cosmic dust.

# DustPedia

The project has received funding from the European Union's Seventh Framework Program for research, technological development and demonstration under grant agreement n°604320.

This image displays all 847 DustPedia galaxies; every galaxy within 140 million light-years of us (that has an angular size over 1/60th a degree) that was observed by the *Herschel Space Observatory*. In each RGB image, red is far-infrared *Herschel* data showing emission from cold interstellar dust; green is near-infrared SDSS data showing light from oscillations of older stars; and blue is ultraviolet *GALaxy* data showing emission from newborn stars. Each image is scaled to the critical size of galaxy down to a minimum of 1/20th a degree. Images with "crackled" red data are where foreground dust or background galaxies outshines the target galaxy.
