MHD EQUATIONS

The core MHD equations consist of: (Krall & Trivelpiece 1973)

Theorem

Continuity Equation (Mass Conservation):

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = 0$$

where ρ is the mass density, and ${\bf v}$ is the fluid velocity.

Theorem

Momentum Equation (Navier-Stokes Equation with Lorentz Force):

$$\rho\left(\frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v} \cdot \nabla)\mathbf{v}\right) = -\nabla p + \mathbf{J} \times \mathbf{B} + \nu \nabla^2 \mathbf{v}$$

where p is the pressure, **B** is the magnetic field, $\mathbf{J} = \nabla \times \mathbf{B}/\mu_0$ is the current density, ν is the kinematic viscosity, and μ_0 is the permeability of free space.

Your Name

MHD EQUATIONS

Theorem

Induction Equation (Magnetic Field Evolution):

$$\frac{\partial \mathbf{B}}{\partial t} = \nabla \times (\mathbf{v} \times \mathbf{B}) + \eta \nabla^2 \mathbf{B}$$

where $\eta = \frac{1}{\sigma \mu_0}$ is the magnetic diffusivity, and σ is the electrical conductivity.

Theorem

Incompressibility Condition (if applicable):

 $\nabla \cdot \mathbf{v} = 0$

Many MHD turbulence studies often assume this condition to simplify the analysis.

"Particle distributions near equilibrium."

Based on the kinetic theory, when a gas is in equilibrium, its velocity distribution follows a Maxwellian distribution.

$$f(v) = 4\pi \left(\frac{m}{2\pi K_B T}\right)^{1/2} v^2 e^{-\frac{mv^2}{2K_B T}}$$

Instabilities

We return to the MHD equations and look for wave solutions, but this time, we assume that the wave has an imaginary part.

$$\omega = \omega_A(k) + i\gamma_k$$

introducing this term on the wave formulae

$$B_1 = B_0 \exp(-i(\vec{k} \cdot \vec{r} + \omega_A(k)t) + \gamma t) = [B_0 exp(\gamma t)]exp(-i(\vec{k} \cdot \vec{r} + \omega_A(k)t))$$

 $\gamma>0$ growth and $\gamma<0$ damping

э

How to stabilize the unstable wave spectrum?

We deal with nonlinear wave-wave coupling within weak (wave) turbulence (Vedenov, 1963).

Let's represent the three interacting waves using their amplitudes, denoted as B_1 , B_2 , and B_3 . Each wave is characterized by its frequency ω_i and wavenumber \vec{k}_i , for i = 1, 2, 3. The conditions for a resonant three-wave interaction are: Frequency Matching Condition:

$$\omega_1 = \omega_2 + \omega_3$$

Wavenumber Matching Condition:

$$\vec{k}_1 = \vec{k}_2 + \vec{k_3}$$

These conditions ensure that energy and momentum are conserved in the interaction.

イロト 不得 トイヨト イヨト

Stabilizing wave growth in weak turbulence

Governing Equations for the wave amplitudes: A set of coupled differential equations governs the evolution of the complex amplitudes $\vec{B}_1(t)$, $\vec{B}_2(t)$ and $\vec{B}_3(t)$. These are typically derived from the governing equations of the medium (e.g., fluid equations, Maxwell's equations) using perturbation theory or a multi-scale analysis. see wave interaction Collisions and wave-particle interactions thermalize the particles in the end. **Example:**

Bump-on-tail instability

Main points on life far from equilibrium

- When in an unstable system, the magnetic fluctuations are equal or larger than the ambient magnetic (strong turbulence), coherent structures replace the linear waves
- Coherent structures are Current Sheets (**CS**), magnetic filaments, large amplitude magnetic disturbances, vortices, and shocks (Vlahos & Isliker 2023)

PROPOSAL: Identification and Characterisation of Coherent Structures (CoS) in 3D strong turbulent plasma

We will try to identify and characterize Coherent Structures (CoSs) appearing in 3D magnetohydrodynamic (MHD) turbulent plasma and satellite data. We propose developing numerical tools based on trained and physics-informed neural networks to identify and characterize all CoSs inside the 3D turbulent simulations and observations.

Strong Turbulence and particle heating and acceleration

In systems close to equilibrium, the energy distribution is close to Maxwell's equation (Thermal distribution). In systems far from equilibrium where strong turbulence is present, the nonthermal particles appear in the tail of the energy distribution.

The non-thermal Universe

- Solar Atmosphere (Coronal Heating, Flares, Coronal mass ejections)
- The solar wind, Bow shock magnetosheath, and magnetotail
- Cosmic Rays
- Nonthermal radiation (Gamma and X radiation sources)

メロト メタト メヨト メヨト

Life close to equilibrium

Linearly unstable waves and weak (wave) turbulence $B_1/B_0<<1$ are mathematically tractable but not realistic for very active space, astrophysical, and laboratory plasmas

Life far from equilibrium

When the unstable waves reach the level where the magnetic fluctuations $B_1/B_0 > 1$, coherent structures appear and are distributed in space

Coherent structures are heating the bulk and acceleration of the tail on most space, astrophysical, and laboratory sources which are far from equilibrium

Fermi and the two energization mechanisms: Stochastic and systematic

The stochastic interaction of particles with coherent structures is behind the bulk heating, and systematic acceleration is responsible for the formation of the high-energy tail.

Tracing particles inside strong turbulence, we discover the Kappa distribution (heating and the high energy tail).
